

Flu shot acceptance: learning from a previous pandemic

A hand wearing a white latex glove holds a medical syringe horizontally. The syringe has a clear barrel with yellow liquid inside, marked with numbers 1 through 4. The needle is thin and pointed to the right. The background is a light blue gradient.

Improving public health by identifying targets for vaccine uptake promotion

Christina Rudolf, Raymond Boateng, Juliane Berek

Setting the Scene: The H1N1 Pandemic

- Pandemic of swine influenza, caused by **H1N1 influenza** virus
- **June 2009 to August 2010** (according to WHO declaration)
 - Most recent pandemic prior to COVID19

President Barack Obama being vaccinated against H1N1 flu on 20 December 2009 © Public Domain

Setting the Scene: The H1N1 Pandemic

- Real number of cases estimated
11 - 21% of the global population
- Total number of deaths in the U.S. was 12,469

Weekly cases of H1N1 vs. all influenza cases (US)

Objectives

- **Increasing vaccination rates** for seasonal and pandemic flu in the overall population
 - **Reducing the burden of influenza** by decreasing hospitalisations/ deaths

- Identify **factors** that determine the chance of **getting vaccinated**
- Identify **groups with lower likelihood for getting vaccinated**, in order to target them with promotions

- Determining differences of seasonal vs. H1N1 (pandemic) vaccinations

Data Overview

Our Sample: 27.000 Respondents

- **Data** was **collected** through the **National 2009 H1N1 Flu Survey** in the U.S. between 2009 - 2010
- Dataset:

Vaccination status

- H1N1
- Seasonal flu

Demographics

**Attitudes and
knowledge**

about H1N1 and seasonal flu

Healthcare Information

The Sample - 27,000 of the US population

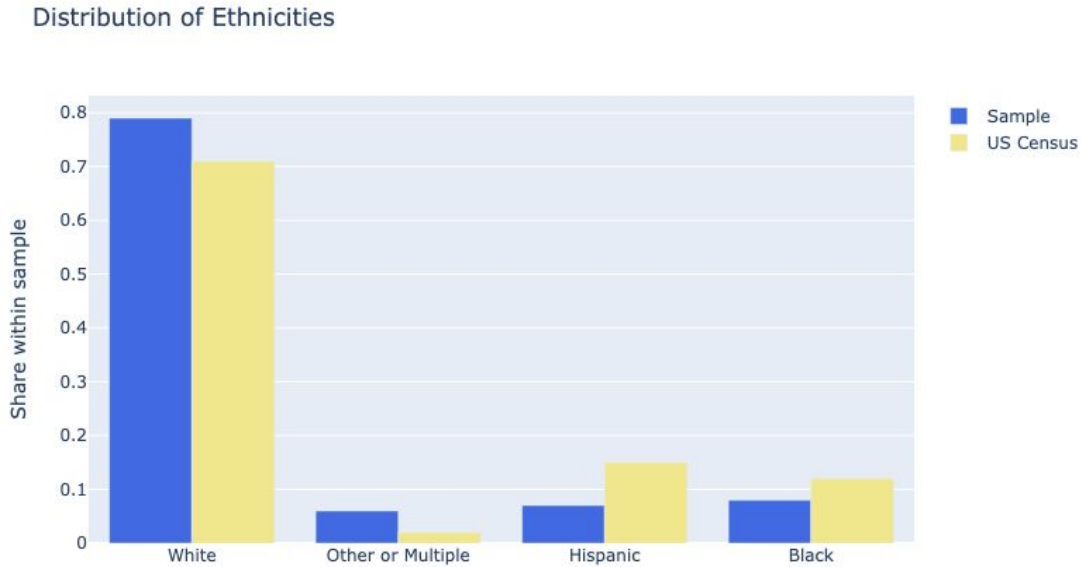

The sample is biased towards older population.

Ethnicities

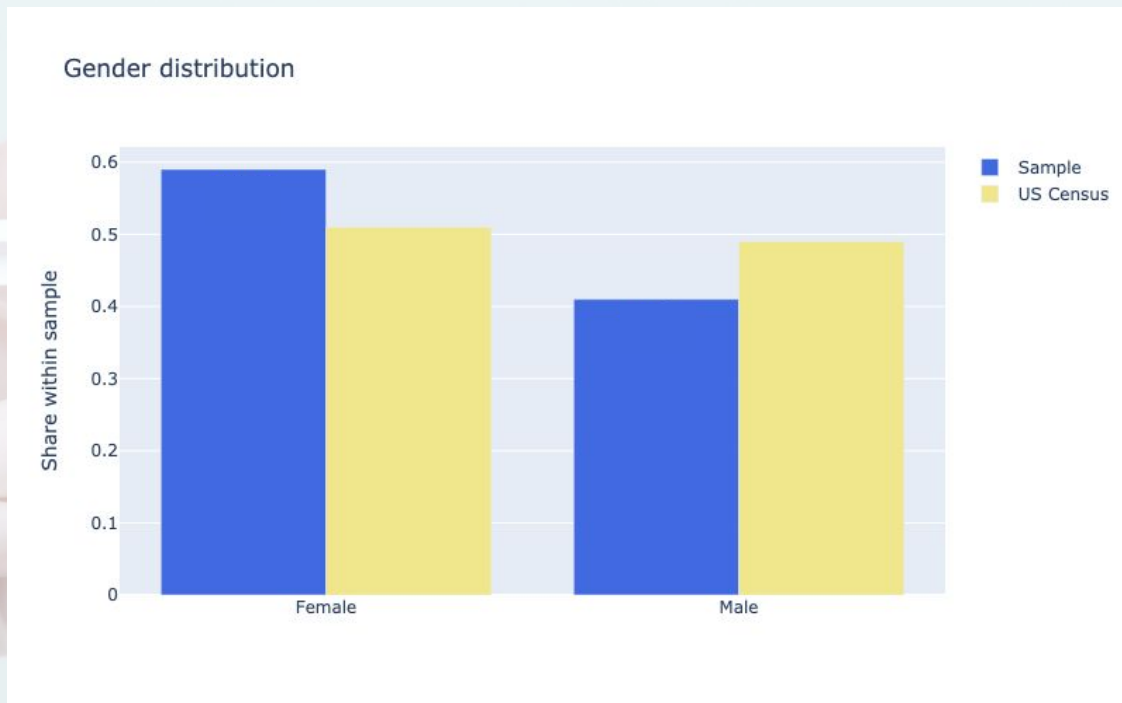

Non-white population is underrepresented.

Gender

Men are underrepresented.

Hypotheses

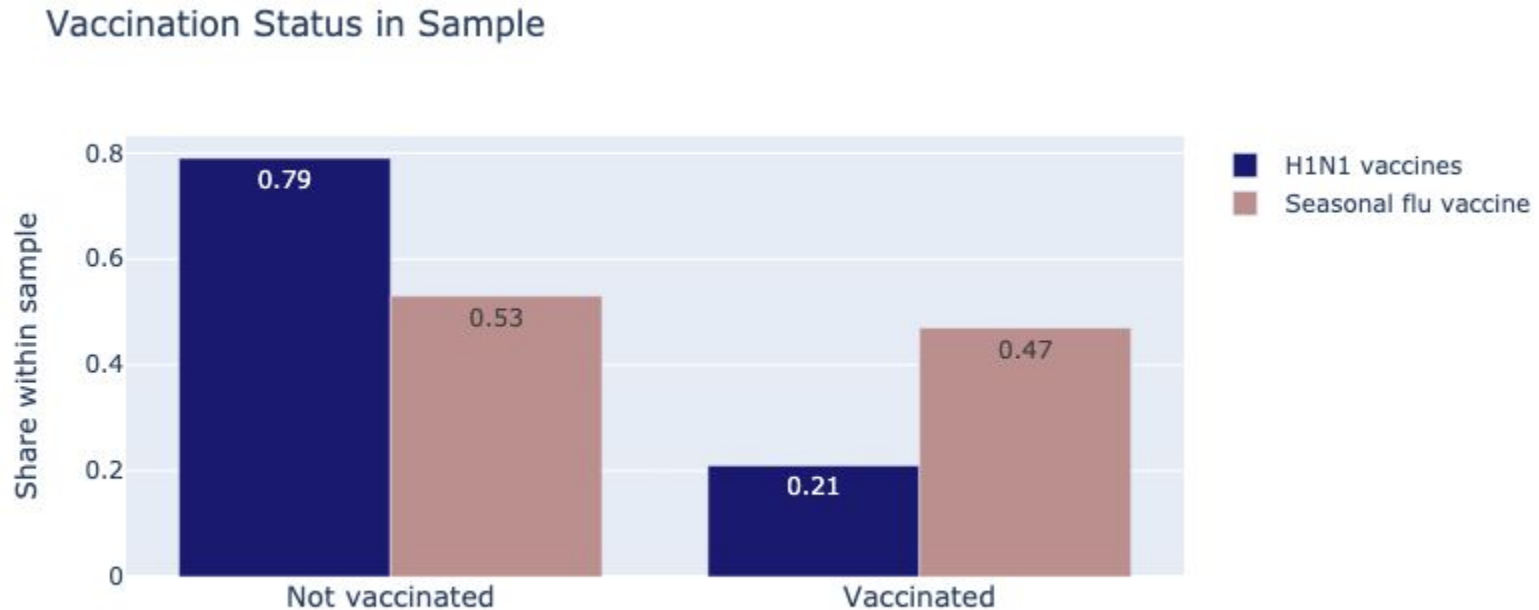

- **Some features affect the likelihood** of vaccination **more than others**, e.g. attitudes and knowledge, recommendations by doctors
- **H1N1 vaccination is taken more** due to the pandemic context

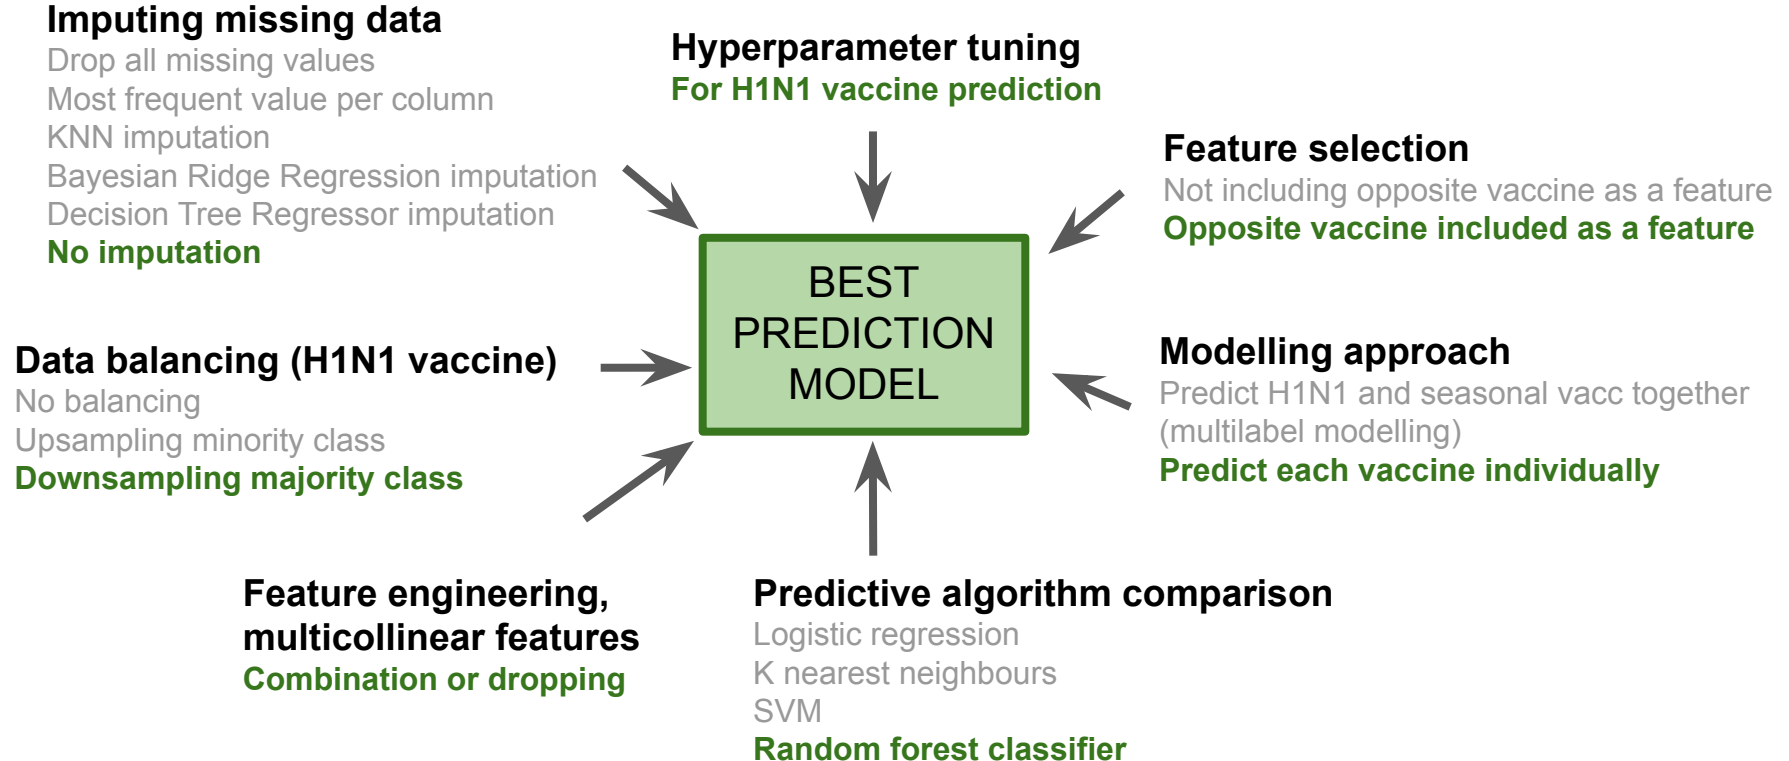

Distribution of H1N1 and Seasonal Flu Vaccines

The seasonal flu vaccine is taken more than the H1N1 flu vaccine

Overview of Prediction Model Development

Outcomes of Our Model

Performance of Best Prediction Model

How to decide on best model?

→ AUC score

H1N1 flu vaccination prediction

AUC score 0.81

Seasonal flu vaccination prediction

AUC score 0.8

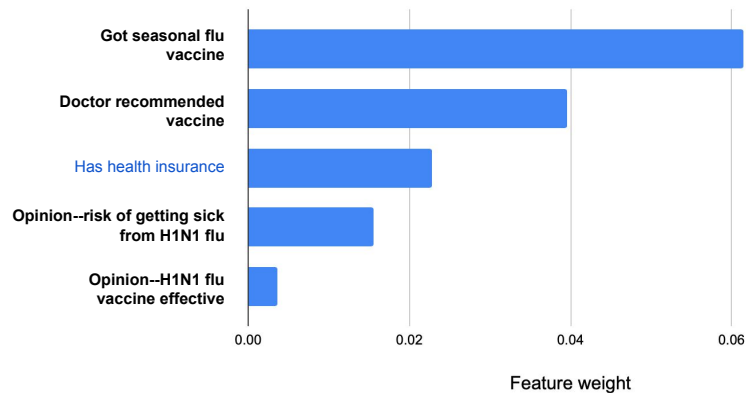

Why do we want a prediction model?

To identify important features for vaccine uptake!

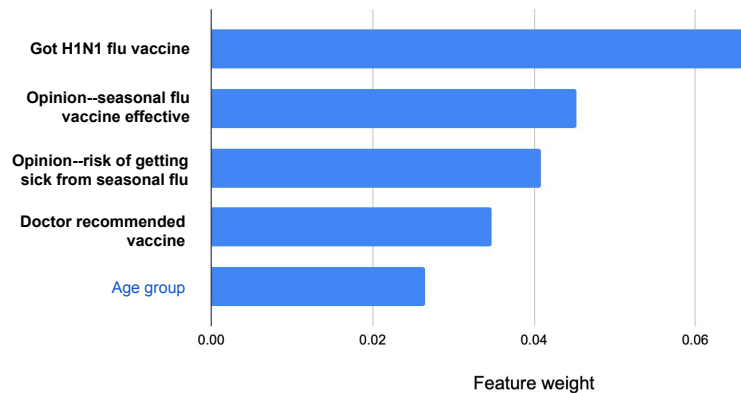

Important Features for Vaccine Uptake

H1N1 flu vaccination, top 5 drivers

Seasonal flu vaccination, top 5 drivers

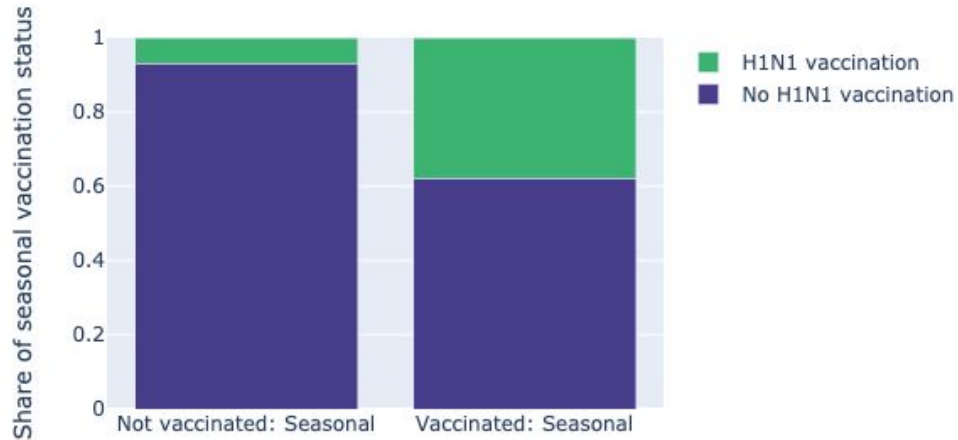

Effect of Taking the Other Vaccine

Taking the other vaccine corresponds with **greater uptake** of our vaccine of interest

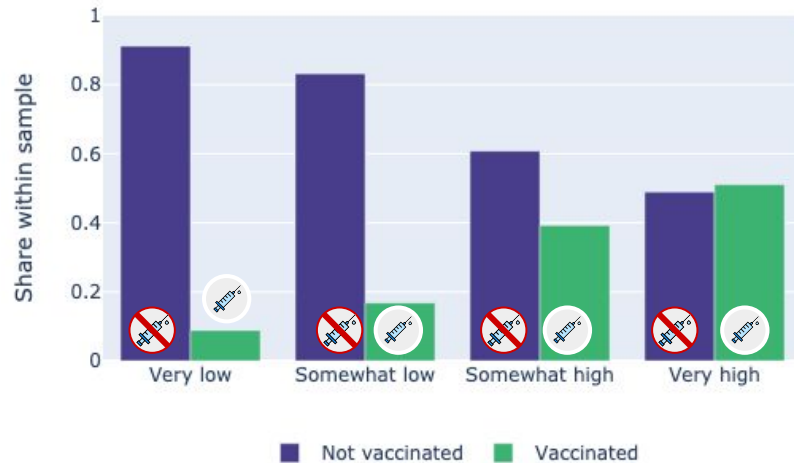

H1N1 vaccination status by seasonal vaccination

Risk Perception Increases the Uptake of Vaccinations

Perceived Risk of H1N1 w/o Vaccination

Perceived Risk of Seasonal Flu w/o Vaccination

Positive Effect of Doctor's Recommendation

Doctor's recommendation, H1N1 vaccine

Doctor's recommendation, seasonal flu vaccine

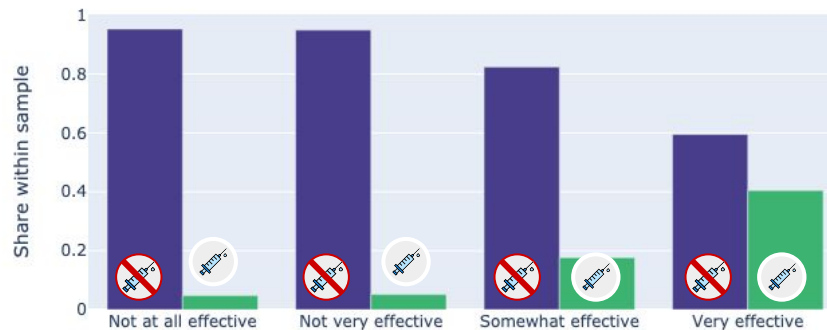

Opinion of Vaccine Effectiveness

A higher opinion of whether a vaccine is effective leads to higher vaccination rates.

H1N1 vaccine

Seasonal flu vaccine

DON'T PANIC

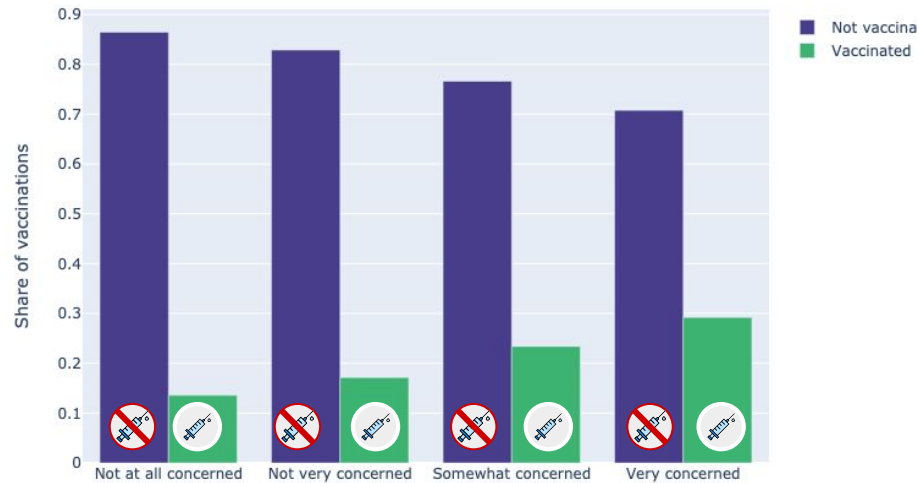

Lessons for a Pandemic

Concerns and knowledge

Increased concern and knowledge about H1N1 flu leads to greater vaccination uptake

Concerns about H1N1

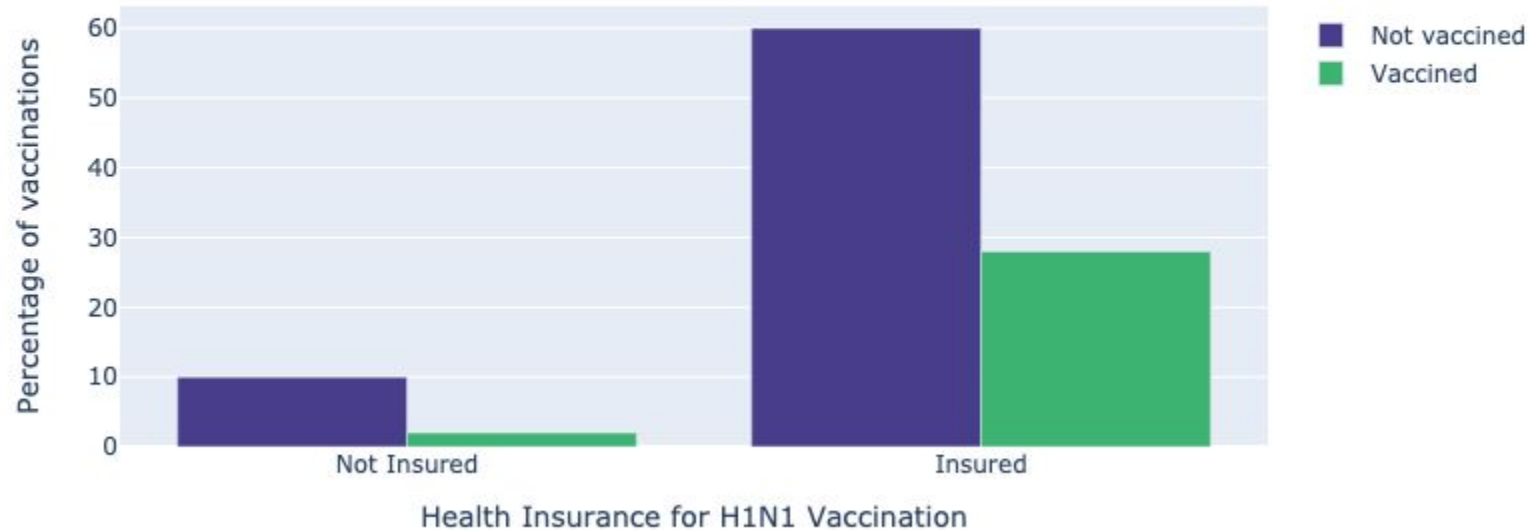

Knowledge about H1N1

Impact of Health Insurance

Having health insurance coverage has a big positive impact on H1N1 vaccination rates

Summary

- **Uptake of seasonal flu vaccine is greater** than of the H1N1 vaccine
- **Some features are predictive** of getting vaccinated
- Certain **features** seem to be **more important in a pandemic context** (for H1N1 vaccine)

Recommendations

- **Raising awareness** of just how contagious each flu is can encourage people to get vaccinated
- **Encourage doctors** to actively recommend the vaccines
- **Educational campaign** to promote the effectiveness of the vaccine
- Additionally, in a pandemic:
 - Education about the **risks of pandemic disease**
 - Ensuring good **health insurance coverage**

Future work and perspectives

- Explore potential **endogenous variables**
- **Cluster analysis** to identify groups with low vaccination rates
- **SHAP analysis**--what features are important on an individual level?
- How do our predictions **translate to disease burden** from influenza?

Back-up slides

Performance of Best Prediction Model

H1N1 flu vaccination prediction

AUC score 0.81

Seasonal flu vaccination prediction

AUC score 0.8

Data completeness and imputation strategy

- Five features have complete data
- Four features have >10% of data missing
- Imputation strategies were compared
- Best outcome: using raw data

Imputation/data cleaning techniques

1. Drop all missing data

- Dropped columns with too many missing values ('health_insurance', 'employment_industry', 'employment_occupation', 'income_poverty', 'marital_status', 'employment_status')
- Next, dropped all rows with null values
- 26707 values → 21853 values

2. No cleaning/imputation

3. Imputation with most frequent values per column (SimpleImputer)

4. Multivariate imputation--KNN (KNNImputer)

5. Multivariate imputation with IterativeImputer (default--ridge regression)

6. Multivariate imputation with IterativeImputer (decision tree classifier)

Imputation/data cleaning techniques--outcomes

Outcome = logistic regression, multilabel prediction

	AUC, H1N1 vaccination	AUC, seasonal flu vaccination
Drop all missing data	0.69	0.78
No cleaning/imputation	0.72	0.78
Imputation with most frequent values per column	0.69	0.78
Multivariate imputation--KNN	0.68	0.78
Multivariate imputation, ridge regression	0.69	0.77
Multivariate imputation, decision tree classifier	0.68	0.78
